Feast, Food and Fodder in Neolithic-Bronze Age Greece: Commensality and the Construction of Value

This paper explores the relationship between mundane domestic and more formal meals in recent rural Greece, as a prelude to a diachronic examination of the range of commensal behavior through the Neolithic and Bronze Age of the same region. Analysis of recent practices highlights the role of a hierarchy of low- to high-value foods. While Neolithic commensality beyond the household emphasizes equality and collective cohesion, formal commensality takes a strikingly and increasingly diacritical form through the Bronze Age. It is argued that Bronze Age diacritical commensality was part of a broader strategy of elite ‘choreography’ of social life. A hierarchy of foods, which linked diacritical behavior, labor mobilization and risk buffering, may have played a critical role in driving this trajectory of change.

Prehistoric archaeology; Bronze Age archaeology; Greece; feast; food; fodder; Neolithic; Bronze Age; value.

1 Introduction

This paper explores the relationship between mundane domestic meals and more formal commensal occasions in Neolithic and Bronze Age Greece, and the role of formal commensality in shaping inequalities of status between participants. It first outlines how

I thank Susan Pollock for the opportunity to take part in a very stimulating meeting in Berlin; Sevi Triantaphyllou for literature on stable isotope analysis in Greece; Valasia Isaakidou for comments on this paper during its gestation; and Susan and two anonymous referees for constructive criticisms of my first draft. The paper draws heavily on collaborative research in Greece with Valasia (on recent and Bronze Age commensality) and with Valasia, Kostas Kotsakis and Duska Urem-Kotsou (on Neolithic commensality).
the recent rural population of Greece used scarce ingredients and culinary elaboration to differentiate between daily meals within the household and commensality on ‘special’ occasions involving hospitality to ‘outsiders.’ A related hierarchy of value (fodder for livestock < food for the poor < food for the better-off) played an important role not only in social differentiation, but also in labor mobilisation and in buffering the uncertainties of agriculture, and thereby ensured close linkage between commensal politics and agricultural production. The paper then addresses similar issues for later prehistory, exploring the role of a hierarchy of foods and commensal occasions in legitimizing and also promoting institutionalized social inequality. It is argued that diacritical feasting, richly documented for the ‘palatial’ later Bronze Age of Greece, developed out of and elaborated on formal commensality in the Neolithic. Key to understanding the causes and significance of this development is the recursive relationship, practical and symbolic, between daily meals and ritual feasts, between low- and high-value foods, and between commensality and agricultural production.

2 Commensality in Recent Rural Greece

This study of commensality in prehistoric Greece begins with discussion of the twentieth century AD, because the recent past offers richer opportunities to investigate both subtle details of commensal provision and the dynamic interplay between the latter and household agricultural strategies. The results of this investigation are applied to the distant past heuristically, as a source of questions rather than ready answers about commensal politics in Neolithic and Bronze Age Greece. Some initial clarification is also necessary concerning the scope of the following discussion of commensal practices in recent rural Greece. First, recent refers to the mid-twentieth century, a period within living memory but before widespread domestic refrigeration, so that the range, seasonality and ‘shelf-life’ of foods were limited by preserving techniques that bear comparison with later prehistory. Secondly, and for similar reasons, the focus is rural, because villagers tended to consume what they produced and preserved, with limited access to the more varied foods and tastes available to some urban dwellers. Thirdly, because published folkloric and culinary sources tend to emphasize regional traditions and food for special occasions, first-hand interviews with (and, to some extent, participant observation of) elderly villagers are the primary source used to sketch a general model of how daily meals were differentiated from formal commensality. Finally, the focus on Greece reflects not imagined culinary continuity from prehistory (although the diet of recent and prehistoric farmers faced similar climatic constraints), but the author’s relative familiarity with Greek cuisine.

2.1 Family Meals and Household Hospitality in Rural Greece

The principal staple element of everyday domestic meals within the household was bread, home-baked on a roughly weekly cycle, or bread and rusks (παξίματα) baked at longer intervals. Depending on region, season and time of day, this was accompanied by relishes such as cooked pulses, cheese, eggs, olives, pickled vegetables, fresh salad, boiled gathered greens, or mushrooms; wine too was often consumed on a daily basis. Poorer households consumed more bread and fewer relishes, while their better-off neighbors enjoyed a more varied diet.

This simple fare was progressively elaborated on more formal occasions, when the household typically played host to a larger social group on a weekly (Sundays), annual (e.g., Easter) and generational (e.g., weddings) timescale. On Sunday, as the day of rest, the household might receive visitors—perhaps relatives from other villages. The main meal on Sunday was often differentiated from that on working days by addition of meat.
(a chicken or rabbit or preserved pork) or more elaborate cereal foods (perhaps cracked wheat—[τριγονάρι = bulgur], Cretan [χύντρο = pilaf]; or savory or sweet pies made with thin fillo [γύδιλο = pastry]). At Easter (and some other annual festivals), households might entertain affinal or ritual kin (e.g., parents-in-law, god-parents, god-children), making a gathering of one or two dozen persons, and differentiated this social occasion by provision of fresh meat (commonly roast lamb or kid) and elaboration of cereal foods (e.g., pies with meat rather than cheese or vegetable filling; wheaten bread, if the daily staple was barley). Weddings might bring together several dozen or even a few hundred relatives, neighbors and friends, and were ideally marked by generous provision of fresh meat (typically roast or boiled sheep or goat) and very elaborate cereal products (e.g., decorated loaves, sweets).

Daily, Sunday, Easter, and wedding meals thus constitute a hierarchy of commensal occasions, of decreasing frequency and increasing number of participants and social significance. Higher-level occasions combined Goody’s ‘African’ (abundant provision) and ‘Eurasian’ (haute cuisine, with scarce ingredients and elaborate preparation) strategies of commensal celebration. The importance of abundance (‘if it is not too much, it will not be enough’) is highlighted in Greek commensal practice by leaving food on one’s plate to indicate satiation. The most important scarce ingredient was fresh meat, usually roast but sometimes stewed, depending on species and age of animal. Some elaborate forms of preparation, such as heavily decorated wedding loaves or sweets, may have copied urban haute cuisine. Others may have been rural refinements: flour for pies passed through a finer sieve than that used in bread-making, to remove more bran; whiter pilaf produced by beating moistened grain to strip off the outer surface (in the manner of pearled barley); and ‘split’ pulses (γύδια) hand-milled to remove the outer seed coat, facilitating cooking and digestion (but reducing volume).

2.2 Inequality in Diet and Hospitality

The scale and culinary elaboration of commensality depended not only on the importance of the occasion but also on the means of the host. While better-off farmers fairly regularly ate at least preserved meat (e.g., sausages, pork sealed in fat) for weekday meals, the poorest might not have meat even for major festivals. As one informant recalled of his childhood in an almost landless household in the north Greek village of Assiros, “sometimes an uncle gave us a joint of meat at Christmas or Easter, but much of the time we waited impatiently for the weddings of the big landowners for the chance to eat a little meat.” Differences in provision between richer and poorer villagers thus paralleled and cross-cut those between commensal occasions of greater and lesser significance.

As the account from Assiros makes plain, social inequalities in the quantity and variety of food available significantly affected villagers’ sense of well-being, with lack of access naturally felt most by those who saw neighbors enjoying prized foods such as meat. Inequalities in the ability of households to offer hospitality also played a significant role in shaping social standing and future economic well-being. As elsewhere in the Christian Mediterranean, many Greek households slaughtered a pig or two in winter and preserved much of its carcass. Informants frequently rationalize this custom in terms of needing meat for unexpected guests: “there were no telephones, so visitors turned up without warning.” Likewise, some women kept a small store of ground bulgur, dried fillo pastry or home-made pasta so as to provide hospitality to visitors without delay. The quality

1 Goody 1982.
2 e.g., Psilakis and Psilaki 2001.
of hospitality provided was a measure of a household’s economic standing and, together with indices such as the clothes worn to church by family members or the appearance of work animals, could be a form of ‘credit rating’ that influenced marriage, ritual kinship, or commercial alliances. Creating a good impression in hospitality was important, therefore, not only to a household’s prestige and social standing, but also to its future economic success.

A well-stocked larder was also important in securing the short- and long-term hired labor essential for large-scale surplus production. Landowners frequently provided daily meals, as well as pay, to seasonal workers from other villages and to long-term farmhands who became temporary household members. Landowners and laborers alike often refer to such provision with the same term (‘I feed,’ ταζω) as for giving food to children and fodder to livestock. A reputation for ‘feeding’ well helped secure the best workers: in north Greek Paliambela-Kolindrou, an informant recalled that “we preferred to work for someone who fed well;” a neighbor, brought up in a household that employed two hired hands continuously and others seasonally, recounted how her father “killed two pigs at Christmas and made lots of cheese because we had workers to feed.” In this region, the larger landowners were known as tsorbatzídes (τσορμπάτζις—literally, ‘soup-makers’ in Turkish), because they fed workers well.

### 2.3 Food and Fodder, Feast and Famine: the Flexible Values of Staple Grains

Domestic production of white flour or ‘pearled’ bulgur was time-consuming, but also ‘wasteful’ of staple grains. The amount of bran removed was variable, ranging from perhaps 10% by weight of the milled grain for ‘black’ bread, through 20–30% for ‘white’ loaves, to nearly 50% for pies and sweets, so a household of five persons routinely consuming white bread might have sacrificed half or even all the grain requirement of an adult. To put this figure in context, fattening a pig is often said to require as much grain as maintaining an adult human and is also roughly comparable to the amount of grain needed to feed a draught ox engaged in heavy work (although livestock usually received grains of lower value). In practice, bran removed from refined cereal products was not wasted, but used in loaves baked for dogs that guarded livestock or mixed with by-products of the dairy, kitchen, or oil-press to fatten pigs. Routine consumption of white bread would be prohibitively costly, however, for any household not achieving significant overproduction of grain. The processing of cereals thus created a hierarchy of value: bran destined for animal fodder < unrefined grain products for routine human consumption < and refined grain products for consumption on festive occasions or by the relatively wealthy.

A similar hierarchy can be discerned among staple grain species. Of the principal cereals grown in Greece, oats were almost universally regarded as fodder; barley, maize, common millet, and rye variously as fodder or food for the poor; and free-threshing bread or durum wheat and rice as food for human consumption, if not reserved for special occasions or privileged persons. Likewise, of the pulse crops, common vetch (Vicia sativa) and bitter vetch (V. ervilia) were almost invariably fodder crops; broad bean (V. sativa) and grass pea (Lathyrus sativus) of ambiguous status; and lentil (Lens culinaris), pea (Pisum sativum), chickpea (Cicer arietinum), black-eyed bean (Vigna unguiculata), and various New World beans (Phaseolus spp.) normally destined for humans. This ranking varied geographically. For example, in the semi-arid southeast Aegean, including much of Crete, rainfall is at the margins of viability for growing wheat, consumption of which was often restricted to bread offered in church at Christmas or Easter and to small quantities of groats served largely on special occasions; barley was the staple cereal for much of the
rural population and was often too scarce for use as fodder. Einkorn, too, was animal fodder or food of the poor in northern Greece, among refugees from Bulgaria, before its cultivation was abandoned, but (like other glume wheats) it retains high status in a few localities around the Mediterranean through association with valued traditional dishes. Despite such regional and local variability, a hierarchy of grains seems to have been universal, and relative rankings of species were reasonably consistent. In part this reflected the diffusion of cultural preferences, such as for white ‘French’ bread, the modern product of urban bakers, over dark, homemade ‘village’ bread. On Crete, this preference extended to growing spring barley, which produced lighter-colored flour than the more reliable and higher-yielding winter barley, as a substitute for wheat in liturgical loaves for Christmas and Easter. These relative rankings also had a practical basis. Free-threshing wheat needed more favorable soil and climatic conditions and was thus harder to grow than the darker cereals; if not highly valued, it would presumably have fallen out of cultivation rapidly. Similarly, pulses primarily destined for human consumption tended to have lighter-colored, thinner, and less toxic seed-coats and so were more appealing (in appearance and digestibility) and less harmful, but also more vulnerable to field- and storage-pests, than their fodder counterparts.

While the grain hierarchy helped differentiate mundane from special meals, its flexible application had additional significance. During the hungry winter of 1941–42, when many urban dwellers died of starvation, some rural inhabitants were reduced to eating fodder crops (e.g., toxic bitter vetch) or previously discarded cereal by-products (bran, even chaff). Others, accustomed only to wheaten bread, ate barley or maize that they normally fed to livestock. Less dramatically, in peacetime, poorer farmers routinely adjusted the grain rations of working cattle, fattening pigs, or breeding and milking sheep and goats, according to availability. After a good harvest, well-fed livestock worked better, put on more fat and produced larger offspring or more milk. After a poor harvest, with ambiguous food/fodder grains diverted to humans, livestock received ‘maintenance’ rations of straw and pasture. The grain hierarchy made rural food supply more reliable in three ways. First, use of low-ranking grains as fodder maintained an incentive to overproduction, even after a run of good years, and thus reduced the risk of scarcity following a bad harvest. Secondly, the loss of face associated with eating low-value grains was a powerful disincentive to consuming them in good times and so undermining their role as safety net in bad times. For example, elderly villagers in Greece can still name the neighbors who resorted to demeaning ingredients for bread in the winter of 1941–42. Thirdly, households in need could exchange modest amounts of high-value grain (or livestock) for larger quantities of low-value staples. For example, in the 1930s in the Cretan village of Aloides, a farmer with a large family and limited land received news that an émigré relative had paid for a quantity of wheat to be available for collection from a merchant in the town. To the bitter disappointment of his children, who longed for white bread, he exchanged the wheat for a substantially larger amount of barley.

Recent rural communities in Greece used scarce ingredients and culinary elaboration to signal commensal occasions of varying cultural and social significance. Foods for special occasions might entail significant investment of labor and also of staple grains—whether in refining the latter (by removing bran or seed coats) or in feeding them to livestock. Generous and elaborate hospitality was thus a source of symbolic capital for the host, an index of economic well-being, and a means of mobilizing labor. A hierarchy of food values also provided a strong cultural incentive to overproduction and, for the less well-off, opportunities to ‘trade down’ high-value resources for larger quantities of lower-value alternatives and so compensate for any shortage of dietary staples. This

5 e.g., Halstead 1990.
hierarchy was thus central to, and strengthened the linkage between, diacritical use of food, inequalities of access to human labor, and buffering of risk to staple resources (Tab. [ ]). The potential significance of this linkage to prehistoric farmers in Greece, as a means of both stabilising household economies in the short term and promoting social inequality in the long term, is considered at the end of this paper.

3 Food and Commensality in the Neolithic of Greece

Charred seeds and animal bones from Neolithic sites in Greece are heavily dominated by domesticates (cereal and pulse crops; sheep, goats, cattle and pigs), identifying farming as the basis of human subsistence. Known Early ('EN') and Middle ('MN') Neolithic sites of mid 7th—early 6th millennium BC date occupy fertile lowlands especially in the east-central mainland. Most were small villages (perhaps a few dozen inhabitants), often long-lived and closely spaced, apparently occupied year-round, and so sustainable by small-scale crop husbandry or by large-scale stock husbandry with an emphasis on dairying. The invisibility of these early farmers in the palynological record, however, suggests modest numbers of livestock, as does the predominance of sheep in a wooded environment to which cattle, pigs and goats were better suited. Moreover, slaughter of juvenile and subadult rather than infant males would have maximized availability of meat rather than milk from domestic ruminants, thus limiting their overall productivity in calories. With livestock managed non-intensively and on a modest scale, early Neolithic villagers must overwhelmingly have depended on grain crops.6 In the Late ('LN') and especially Final ('FN') Neolithic (late 6th–4th millennium BC), habitation proliferated in the semi-arid, agriculturally marginal southeast mainland and Aegean islands, mostly as small ‘hamlets’ housing perhaps up to two dozen persons. Although such dispersed settlement would have made reliance on livestock more feasible, available mortality evidence again indicates non-intensive ‘meat’ management, coupled with small-scale and stationary rather than large-scale and seasonally mobile herding, and so favors subsistence dependence primarily on crops.7 Pathological and stable isotope evidence from LN and FN human skeletal remains, at the village settlement of Makriyalos in the north8 and at ‘marginal’ hamlets and caves in the southeast9 alike, is consistent with dietary dependence on grain. Accordingly, the following discussion assumes that livestock, though important to crop production for manure and labor,10 were secondary to grain crops in contribution to human diet.

3.1 Daily Meals in the Neolithic

Early villages were comprised of houses and huts of variable form, construction and size,11 but more suited to occupation by something like a nuclear or extended family than a larger social group or single person.12 Rare examples of well-preserved, burnt destructions in northern Greece and the neighboring northern Balkans have yielded diverse toolkits and evidence of bulk storage compatible with these structures sheltering ‘households.’13 Cooking pots, in small numbers from the MN and more frequent

thereafter, are of a size suitable for a small family, suggesting consumption of daily meals at a household level. Given the proposed subsistence reliance on grain, cereal- and pulse-based dishes without meat were probably the norm. Traces of ruminant milk and especially of adipose fat from both ruminants and non-ruminants (presumably pigs), in LN cooking vessels from Makriyalos and Stavroupoli, may represent ingredients added to enhance grain-based dishes rather than milk- or meat-based dishes. Gathered fruits and nuts were also probably added as flavorings, but seasonally, as there is scant archaeobotanical evidence for their storage (even though charring can preserve fruits dried for storage as well as cereal and pulse grains). Daily household meals may not have been memorable sensory experiences.

Although ‘domestic’ architecture and cooking vessels suggest the organization of much routine social life at a household level, early farmers in Greece also invested heavily in village solidarity: through collective digging of enclosure ditches; through burial practices emphasizing collective over individual identity; and probably through rituals and dress codes defining age- and gender-based social categories. The spatial organisation and material culture of early farming settlements thus imply a long-term and dynamic tension between collective and domestic solidarity. This in turn arguably reflects contradictions between collective responsibility for clearance, fencing, defence (if needed) and occasional redistribution of cultivable land, on the one hand, and household control of the husbandry, storage and consumption of staple crops, on the other.

Over time, however, a broad trend is detectable towards more monumental domestic architecture and clearer definition of individual households, and this is paralleled by changes in commensality between households.

### 3.2 Commensality between Households in the Neolithic

EN-MN hearths are found both inside domestic structures and in intervening open spaces, implying cooking in private and in public, respectively, with the latter more subject to peer pressure to share cooked food. Access to outdoor hearths was progressively limited

over time, however, as walls or ditches subdivided some LN villages into small groups of neighboring households and the cooking facilities of some FN and Early Bronze Age ('EB'—3rd millennium BC) houses were placed in the privacy of closed domestic yards or even indoor ‘kitchen extensions.’ The implication that peer pressure to share cooked food was progressively suppressed is consistent with LN evidence for dietary inequality between households and individuals: the former reflected in variation in the types of fat residues (milk, ruminant adipose fat, non-ruminant adipose fat) found in cooking vessels at Makriyalos and Stavroupoli; the latter in indications, from isotopic analysis of human skeletons, of variable animal and plant protein intake at LN Makriyalos. Unfortunately, similar evidence is not yet available for the earlier Neolithic.

Despite the suggested trends toward greater household independence and suppression of food sharing, individual households are inviable in the medium and long term and, throughout the Neolithic, must periodically have depended on neighbors for food, labor, and other forms of support. Commensality widely plays a central role in forging and affirming the bonds of kinship and neighborliness that are mobilized to provide mutual help, so the observed trends in domestic architecture and in the location of cooking facilities should reflect not the curtailment of commensality between households but a change in the basis on which it took place. Diachronic changes in ceramic tableware support this suggestion.

Ceramic vessels were absent at the beginning of the Neolithic, at least at Knossos on Crete, and were scarce through the EN. The main function of these earliest vessels, few (if any) of which were used for cooking or bulk storage, was the presentation and consumption of food and drink. In form and surface finish, many early vessels imitated wooden prototypes, which may have been used for everyday meals, while the scarce ceramic skeuomorphs serviced more formal commensal occasions. Given the greater obligation to share cooked than uncooked (stored) food, it may be significant that ‘cooked’ (ceramic) rather than ‘raw’ (wooden) vessels were used in formal commensality. Either way, EN tableware is strikingly uniform in appearance, underlining the equality or collective identity of those bound by commensality.

From the MN onwards, the volume of ceramics discarded was strikingly greater, while cooking and bulk storage vessels progressively made up a significant proportion of the repertoire. Tableware was also much more frequent, however, perhaps now being used also for everyday meals, while a minority of fine and decorated vessels was reserved for more formal commensality. In addition, increasing diversity in the shapes and surface treatments of tableware suggests increasing differentiation of commensal occasions, as perhaps does the diversity of culinary methods implied by LN cooking vessels. MN jars with interiors corroded by storage or transport of an acidic liquid are found widely in Greece and the north Balkans and suggest an important social role for some form of fruit-based or fermented beverage(s). From the early LN in northern Greece, drinking sets, comprising similarly decorated jugs and bowls, suggest that at least some commensal

32 Loughlin 2010; Urem-Kotsou pers. comm.
acts involved ceremonial drinking that perhaps took a standardized form, while grape pressings from Dikili Tash identify wine or grape juice as one of the beverages consumed. A few early LN jars coated on the inside with birch tar imply that some liquids were highly valued. Specific beverages cannot be linked to particular vessel types or contexts of consumption, but vessels similar in shape and surface treatment at sites located dozens of kilometers or more apart indicate replication of drinking ceremonies among communities using different forms of tableware for everyday consumption. Such shared customs in turn imply that drinking ceremonies played a role, *inter alia*, in *inter-*communal social intercourse.

If the carcasses of domestic animals were not a major component of Neolithic diet (see above), then meat, like prestigious beverages, may have helped to differentiate important communal occasions from daily meals. Faunal evidence for timing of slaughter and subsequent carcass processing supports this expectation and adds some important detail. First, most surviving and ageable remains of domestic animals indicate slaughter from the latter part of the first year onwards, with high proportions of sub-adult and young adult deaths; Knossos on Crete illustrates this pattern for all four principal domesticates over the entire Neolithic. The overwhelming majority of animals for which we have evidence was thus killed at an age and carcass size too large for consumption fresh by individual households. Slaughter apparently throughout the year, however, argues against large-scale preservation and storage of meat (only really practicable in the winter months), while traces of butchery and bone fragmentation normally preclude significant wastage of carcasses. By default, carcasses must have been distributed for consumption between multiple households, as bone dispersal at EN-FN Knossos also implies. Here, several excavation units yielded pairs or larger groups of articulating bones that presumably had not been disturbed since discard, but these were exclusively sets of bones not normally separated during butchery (e.g., radius-ulna, phalanx 1–2). Articulating bones routinely separated for cooking or consumption, such as humerus and radius, were not found together, implying that carcasses had been divided and dispersed before bone discard. A similar pattern can be inferred on a smaller scale at Revenia-Korinou and Paliambela-Kolindrou, in northern Greece, where EN pit fills have yielded restorable ceramic vessels, again implying low levels of post-depositional disturbance, but no examples of articulating meat-bearing bones. These examples of pre-discard dispersal of carcasses are widely distributed in space and time and arguably represent a fairly general pattern. Moreover, most of the male (and some of the female) domestic animals represented on Neolithic sites could have been slaughtered younger, without significant sacrifice of secondary products, at a size of carcass more amenable to rapid consumption by a single household. Most Neolithic livestock were not only distributed between households for consumption, therefore, but were probably also reared for this purpose.

### 3.3 Neolithic Commensality: Communal or Regional Feasting?

While consumption of domestic animal carcasses beyond the household was seemingly the norm in the Neolithic, it sometimes involved commensal on a very large scale indeed as at LN Makriyalos I in northern Greece. Unlike the compact ‘tell’ villages...
with substantial houses, Makriyalos is a ‘flat-extended’ settlement, covering 28 ha and characterized by insubstantial domestic architecture (semi-subterranean huts) but heavy collective investment in an enclosure ditch nearly 2 km long. Use of this ditch for initial burial of subsequently scattered human remain highlighted collective identity, while two large quarry pits were refilled with exceptional quantities of commensal debris. Pit 212, the richer of these pits in faunal remains, is discussed here.

The culturally rich basal fill of Pit 212 formed rapidly and, judging from numerous ceramic joins within individual excavation units, did not gradually accumulate elsewhere before secondary deposition in the pit. Accordingly, although the basal fill probably represents consumption over several months (based on ages at death of young livestock), this period is unlikely to exceed a year or two. The pit yielded remains of hundreds of animals (mainly pigs, sheep, cattle and goats) that would have provided a few tens of tons of meat; traces of butchery and of fragmentation for marrow do not suggest significant wastage. Slaughter on this scale, albeit over several months, implies both provision and consumption of animals by a very large social group—perhaps the entire resident community at Makriyalos (the size of which is unknown) or a gathering of the regional population. An appropriate analogy for the commensal activity represented by Pit 212 may be the periodic, inter-communal goat and pig feasts that punctuate multi-annual cycles of herd growth in the highlands of Pakistan and New Guinea.

While standardized cooking and serving vessels ostensibly confirm the collective nature of the Pit 212 ‘feasting cycle,’ several hundred unique small cups, many with zoomorphic handles perhaps signalling the symbolic importance of meat, highlight a contrasting dimension to such commensality. Likewise, the size of these cooking and serving vessels implies both that food was prepared and consumed in family-sized groups and that most carcasses were distributed between several such groups for cooking and serving. Despite the massive scale of commensality that it represents, therefore, Pit 212 reveals simultaneous appeals to collective and domestic solidarity that exemplify the tensions inherent to Neolithic society.

3.4 Neolithic Commensality: Hosts and Guests

Commensality beyond the household was important enough to Neolithic society in Greece to play a significant role in shaping the development of ceramic tableware and, arguably, the management of livestock. Tableware highlights the role of such social occasions in reinforcing collective solidarity, but also hints at a more divisive dimension. The possibility that commensality promoted competition and inequality between households receives some support from the treatment of domestic animal carcasses.

Analysis of butchery marks on domestic animal bones at several sites, using the same recording and quantification protocols, indicates far less frequent traces of dismembering and filleting in Neolithic than Bronze Age assemblages, even though the switch from stone to metal cutting tools probably favored the opposite outcome. Experiments (and common sense) suggest that butchery marks are more likely to be inflicted in cutting raw than cooked meat. At least in an uncooked state, therefore, Neolithic carcasses seem

initially to have been butchered into large parcels of meat. In many if not most cases, these parcels were too big for available cooking pots and were presumably roasted in ovens or pits or next to open fires, incidentally implying that residues of adipose fat found in ceramics indeed result from subsequent use of fat or marrow as flavoring for grain-based dishes. It also implies that much of the distribution of meat, inferred from bone dispersal, took place in cooked form.

The terms under which cooked meat was distributed are difficult, but perhaps not impossible, to disentangle. Differential use of skeletal material as raw materials for tools and ornaments confirms a conceptual distinction in the Neolithic of Greece and the northern Balkans between domestic and wild animals and also, probably, between small game (exploited like domestics) and large game. This recalls Ingold’s contention that the key distinction between domestic and wild animals is that the former belong to someone. The distribution of domestic animal carcasses between households, therefore, probably did not take place on the basis of a generalized obligation to share, as among non-storing foragers, but earned prestige for the households or individuals who owned them and imposed an obligation to reciprocate.

In this context, the ‘delayed’ slaughter of male livestock may have been driven by competitive hospitality between households, with larger carcasses conferring greater prestige. A similar motive probably underlies the fattening of livestock, implied by dental microwear evidence that sheep and goats consumed in the ‘feasting cycles’ at LN Makriya had enjoyed an unusually soft diet in the days preceding slaughter. LN animal dung also indicates consumption by livestock of figs and perhaps cereal grain, although this evidence cannot be related to any particular communal context. That individual households commemorated large communal events is implied by bucra (cattle skulls) that had probably adorned house facades at LN Promachon in northern Greece. At MN Paliambela-Kolindrou, however, selective deposition of animal skulls in (or perhaps their display on the edge of) a MN circuit ditch, together with scattered human cranial fragments, suggests emphasis, at least overtly, on a collective rather than domestic social context.

It would be rash to read too much into the apparent contrast between MN Paliambela-Kolindrou and LN Promachon, but a diachronic shift from covert to overt competition would be compatible with indications of growing household independence through the Neolithic (above). Admittedly, there are also indications that asymmetries between provider and recipient of food were played down throughout the Neolithic. First, if cooked meat was indeed dispersed for consumption, this would have limited display by the host to the phase of carcass distribution, without opportunities for further choreography of the host-guest relationship during commensality in the strict sense of both parties eating together. Secondly, ceramic assemblages play down this asymmetry, as is perhaps most evident in the absence of spouts for pouring on Neolithic jugs. Nonetheless, two related aspects of carcass processing may reveal a significant change in communal politics during the Neolithic. First, EN and perhaps MN faunal assemblages seemingly underwent much heavier pre-depositional fragmentation (including fracturing of small

sheep and goat phalanges) than those of LN and Bronze Age date. As well as enabling more thorough extraction of within-bone nutrients, this also arguably served to homogenize or mask differences between body parts in nutritional or symbolic value. Secondly, in contrast with wholesale and uniform processing of carcasses at EN Revenia-Korinou and Paliambela-Kolindrou, there is evidence from LN Makriyalos for initial dressing of the carcass, involving removal and separate discard of the feet, and from LN Toumba Kremastis-Koiladas for structured deposition of dressed carcasses. Selective treatment of particular body parts and structured deposition of faunal remains are relatively commonplace in FN and Bronze Age assemblages and may have played a significant role in the diacritical use of commensal occasions (see below).

Hints of a shift in the nature of commensal politics, from the earlier to the later Neolithic, are by no means unambiguous, thanks partly to the recent growth of research interest in this subject, and the consequent scarcity of relevant data, and perhaps partly to the ‘noisy’ and disputed nature of the development of household economies and the related tendency for architecture, portable material culture, and commensal debris to present mixed messages. Nonetheless, three temporal trends, admittedly of varying clarity, arguably point in the same direction. First, architecture and the spatial organisation of settlements suggest that the balance between collective and domestic solidarity shifted gradually through the Neolithic in favor of the latter. Secondly, ceramic tableware indicates progressive differentiation of commensal occasions and so, arguably, a tendency for hospitality to become increasingly conditional on social context and the relationship between the parties involved. Thirdly, faunal evidence for carcass processing and discard hints that consumption of animals was attended by greater formality or ceremony in the later Neolithic, with earlier emphasis on equality between consumers giving way to restrained highlighting of inequality among providers.

4 Bronze Age Commensality

A combination of archaeobotanical, palynological, zooarchaeological, and textual evidence shows that the Neolithic repertoire of domesticates was enlarged in the Bronze Age, most strikingly by tree crops (olive, fig, probably walnut, and chestnut), spices, and horses, donkeys, and mules, although there is no evidence that any of these additions made a quantitatively significant contribution to Bronze Age diet. The range of securely attested cereal and pulse crops also expanded, with firm archaeobotanical evidence for cultivation of spelt wheat and free-threshing bread wheat particularly notable (see below) given that these displaced the Neolithic glume wheats across much of Europe during the Iron Age. Plant and animal remains from Bronze Age settlements again suggest grain crops and the initial suite of livestock species as the main sources of human nutrition, while the number and size of settlements and lack of specialized ‘milk’ mortality in domestic ruminants again leave little doubt that grain crops were the dietary mainstay. There is Bronze Age archaeobotanical evidence for preparation of split pulses and of both coarsely ground groats and finely ground flour from cereals. The Neolithic record is too sparse for archaeobotanical demonstration (or rejection) of changes in food preparation techniques. In contrast with bread wheat (first securely documented, if not introduced, in the Bronze Age), however, the staple Neolithic glume wheats (emmer, einkorn, ‘new’ type) are usually considered better suited for making groats than bread. Stable isotope
analyses of human skeletons of Early (‘EB’), Middle (‘MB’) and Late (‘LB’) Bronze Age
date are compatible with higher levels of animal protein intake than in the Neolithic.\(^{64}\)
On present evidence, however, this could equally reflect reduced dietary importance
of pulses relative to cereals\(^{65}\) or increased manuring of staple grain crops\(^{66}\) or heavier
skewing of surviving human remains to a privileged minority.

While collective efforts to assert equality and solidarity perhaps obscured the
degree of inequality in Neolithic society, hierarchical distinctions within and between local
communities were prominently displayed especially in the ‘palatial’ later Bronze Age
of southern Greece. Macroscopic study of LB human skeletons from the Pylos region
has revealed differences between individuals in physical well-being that seem correlated
with mortuary evidence (grave type and associated goods) for social status,\(^{67}\) while stable
isotope analysis suggests that elite individuals in Grave Circle A at Mycenae enjoyed
very privileged access to animal (including marine) protein.\(^{68}\) At the other end of the
spectrum, palatial texts listing rations to dependent workers suggest a tedious diet of
grain, sometimes supplemented with figs and perhaps olives.\(^{69}\) Overall, however, a strong
research bias towards elite contexts means that the diet and daily meals of the many have
received far less attention than the ceremonial commensality of the few. Accordingly, this
section begins with later Bronze Age ‘palatial’ banqueting, before attempting to set this
in a wider social and chronological context.

4.1 Diacritical Feasting: Palatial Banquets in Late Bronze Age Greece

One function of the architectural complexes known as ‘palaces,’ in later Bronze Age
southern Greece, was as a venue for formal commensality. The evidence is richest and
most diverse for the LB (later 2nd millennium BC) Mycenaean ‘palaces.’ For example,
structured deposits of cattle bones at the ‘Palace of Nestor,’ Pylos, suggest simultane-
ous slaughter of several large cattle that probably provided sufficient meat to entertain
hundreds—if not thousands—of guests.\(^{70}\) Linear B texts administering palace-organized
banquets also indicate slaughter of multiple domestic animals, some fattened for the pur-
pose, and provision of wine and a range of both staple and uncommon foodstuffs,\(^{71}\) while
stores of ceramic tableware confirm that some large-scale communal events took place
at the ‘palaces’ themselves.\(^{72}\) The palaces provided a built setting for communal events
that was extremely grand, but with access closely controlled by courtyards, doorways,
corridors and partitions,\(^{73}\) and different categories of guests probably penetrated the
complex to different degrees.\(^{74}\) Inlaid dining furniture was provided probably for a small
minority of guests,\(^{75}\) and rank-specific garments, woven in palatial workshops, may have
been distributed as gifts on such occasions.\(^{76}\) Iconography reveals a ‘toasting’ etiquette,
perhaps known only to higher-status guests, while texts record not only scarce food ingredients but also culinary specialists, who presumably produced elaborate dishes for the few rather than the many. The evidence from MB-early LB (early-mid 2nd millennium BC) Minoan palaces is sparser, but numbers and varieties of drinking vessels again imply provision for differential hospitality to the many and the few, while architecture again provided a grand built setting with intensely graded access. Moreover, intensive and highly distinctive butchery of animal carcasses at the Minoan ‘Palace of Minos,’ Knossos, may reflect production of elaborate meat dishes, taking advantage of the variety of cooking methods implied by ceramics and iconography.

In short, palatial banquets were carefully choreographed occasions, with built setting, furniture, dinner services, and probably clothing, etiquette and haute cuisine playing an active diacritical role. Moreover, the structured deposits of cattle bone at Pylos reflect ‘sacrifice’ of selected body parts stripped of meat, but (most unusually) not broken to extract marrow, before being burnt. If this ritual treatment represents ‘sacrifice,’ sensu stricto, it implies divine participation in these commensal events and thus divine approval of the highly inegalitarian social relationships that they perform.

4.2 Bronze Age Diacritical Feasting: Beyond and Before the Palaces

Some of the commensal events recorded in Linear B texts, and thus involving some administrative role for the palace, took place in the modest settings of outlying shrines or settlements. The graded access characteristic of palaces was also replicated on a smaller scale in lower-order settlements, hinting that diacritical commensality was quite widespread in LB society, while Linear B texts account for consumption of only a small minority of the animals that must have been culled annually from recorded livestock, implying slaughter on a large scale in non-palatial contexts. Graded access is also evident in a few earlier monumental buildings, notably at EB Lerna but also at FN Mikrothives and perhaps in the LN ‘megaron’ buildings at Dimini, Sesklo, and Visviki. EB commensality may, as in the palatial context, have highlighted distinctions between different categories of participants, if widespread ceramic skeuomorphs of metal vessels mean that the latter too were used, while jugs with exaggerated spouts that drew attention to the act of pouring arguably emphasized the distinction between host and guest, in stark contrast with Neolithic drinking ceremonies.

The Pylos burnt bone deposits exemplify two aspects of carcass processing—anatomically selective treatment and structured deposition—that are fairly common in the Bronze Age and perhaps FN, but almost unknown in the Neolithic, especially EN and MN (see above, 3.4). Anatomical selection ranged from burnt sacrifice of mandible, humerus and femur at LB Pylos, through retention of femurs in domestic or culinary contexts at LB Pevkakia and Mitrou, to use of femurs and metatarsals as raw material for personal items found in funerary contexts in the EB southern Aegean. In sharp contrast with the

apparently uniform processing of carcasses in the earlier Neolithic, therefore, anatomically selective treatment played a diacritical role in distinguishing between consumers or contexts of consumption, although the beginnings of such selective treatment may be discernible in carcass dressing and separate discard of feet at LN Makryialos and Toumba Krematis-Koiladas. **Structured deposition** included the collection and burial both of selected body parts from several animals, as at LB Pylos, and of the butchered and consumed parts of individual animals, as at LB Knossos, EB Proskynas, and FN Mikrothives. Both forms of structured deposition stand out from the mixed bone refuse that makes up the overwhelming majority of faunal assemblages throughout the Neolithic and Bronze Age in the Aegean and served to highlight the significance of certain acts of consumption. In common with the distinction, evident from LN onwards, between primary carcass dressing and butchery for cooking and consumption, structured deposition helped to emphasize distinct stages in the cycle of slaughter, butchery, cooking, consumption, and discard. Such temporal and perhaps spatial segregation served to ritualize or formalize this cycle, while also enhancing the diacritical potential for restricted categories of people to participate in different stages.

### 4.3 Later Bronze Age Palatial Economies: Feasting and Mobilisation

While Mycenaean palace-sponsored feasting doubtless legitimized elite authority and attracted followers,\(^9^0\) the palace was not the sole contributor of what was eaten and drunk on such occasions. ‘Palatial’ feasting consumed a lot of high-value resources provided by outsiders, as indicated by Linear B records of banquet supplies such as fattened livestock from high-and low-ranking individuals and groups or from local administrative entities,\(^9^1\) and perhaps also reflected in iconographic representations of processions of people bearing gifts or tribute.\(^9^2\) Even when texts do not specify an outside source, it is not clear whether the palace provided or merely collated and distributed banquet supplies.\(^9^3\) The contribution of the palace to ‘palatial’ feasts apparently lay more in the provision of a prestigious venue or celebrity guests than of large quantities of luxury food and drink or high-quality tableware. Guests at the Pylos ‘Palace of Nestor’ were doubtless impressed by the elite ambience, but most were served in plain, mass-produced *kylikes*, the disposable equivalents of modern plastic cups. Even the grain that the palace allocated for feasts or festivals partly represented rations or payments to persons responsible for preparatory tasks\(^9^4\) and anyway was overwhelmingly that represented by ideogram “121 (conventionally ‘barley’), in the production of which the palace apparently played no part.\(^9^5\) In sum, although the balance of palatial versus external contributions is difficult to quantify with such a fragmentary and enigmatic textual record, it is likely that the palaces were heavy net beneficiaries of the feasts and associated gift giving that they sponsored. Indeed, as has been argued elsewhere from combined analysis of Linear B texts and other archaeological evidence, ‘gift’ giving in feasting contexts may have played a major role in palatial resource mobilisation.\(^9^6\)

The terminology of banquet provision texts implies that at least some such contributions were obligatory, and a broad correlation between status of contributor and size of contribution\(^9^7\) suggests that such obligations accompanied high status. While contributions

from low-ranking individuals perhaps sought palatial favor, rank-specific textiles made by palatial weavers may, if distributed at feasts (there is almost no direct evidence for their disbursement), have conferred or reaffirmed high status. The capacity of the palace for resource mobilisation thus rested partly on its ability to define and confer status positions—with attendant obligations of contributions to palatial feasting. That palatial control of the value of people and things played a central role in mobilisation is underlined by the output of palace-sponsored craft production. While many such goods used scarce or exotic raw materials and skilled craftsmanship, high levels of labor specialisation and product standardisation created distinctive value-added artefacts with a 'Palace™' akin to modern 'designer labels.' The capacity of the palace to create value is perhaps clearest in textual evidence for selective use of cereals: ‘120 ‘wheat’ was normally assigned as rations to groups of female workers; ‘121 ‘barley’ for banquets, as religious offerings, in rations/payments for festival preparation and as rations to men; and ‘129 ‘flour’ (of bread wheat?) for banquets, religious offerings and perhaps festivals. Detailed interpretation is obscured by uncertainty as to whether the conventional identifications of ‘120 and ‘121 should be reversed and, in either case, whether the wheat in question was free-threshing bread wheat or glume wheat(s) such as emmer and einkorn. The selective use of different cereals, however, in mundane versus elite/religious contexts and in rations to women versus rations to men, recalls the hierarchy of grain values of the recent past and makes clear the potential for contexts of use and exchange to shape the value of things and people. This potential, in turn, was greatly enhanced by the use of material (e.g., graded-access architecture, elaborate décor, specialist craft goods) and non-material (e.g., religious ritual, etiquette, culinary knowledge) culture to distinguish practically and symbolically between different places, times, forms, and cultural contexts of social encounter.

5 Conclusion: Commensality, Inequality, and the Creation of Value

Palatial feasting in the later Bronze Age southern Aegean was highly diacritical, using a variety of material and non-material means to affirm or confer striking differences of status in an ostentatiously hierarchical society. Conversely, surviving evidence of Neolithic (and especially earlier Neolithic) commensality lacks obvious signs of diacritical behavior. As a corollary of this contrast (which somewhat recalls Goody’s distinction between ‘Eurasian’ diacritical haute cuisine and ‘African’ quantitative emphasis on abundant provision), later Bronze Age feasting was arguably an important mechanism for elite mobilization of resources upwards from those of lower rank, whereas Neolithic commensality could involve massive expenditure of food resources, as at LN Makriyalos, with limited evidence that this was transformed into long-term or salient inequalities of status or rights to resources. The basis of later Bronze Age commensal mobilization, it is argued, was the added value that accrued to commensal events and craft goods by association with the palace and ostentatiously elite material culture; Bronze Age elites exploited their ability to define value regimes as a means of mobilising the material resources and

99 Killen 1985, 238 n 47.

102 Bennet 2008.
105 Halstead 1995b.
labor on which their privileged position depended. Conversely, Neolithic communities invested considerable food resources in commensal acts of collective solidarity that were orchestrated so as to blur rather than highlight inequalities.

This begs two questions. How were commensal practices transformed from a Neolithic force for collective solidarity and equality to a Bronze Age diacritical arena for upwards mobilization? And did commensality play an active part in this transformation or simply project changing cultural values and social relationships? Part of the answer to both questions is that Neolithic material culture, including that associated with commensality, simultaneously highlighted collective and domestic solidarity, reflecting the tension between these two social scales. The transformation from cohesive Neolithic to divisive Bronze Age commensal practices was thus one of degree rather than kind—although the difference was considerable and had radical political, economic, and ideological consequences.

A second part of the answer is that the LB palaces manipulated value regimes by an elaborate choreography of social life, using material and non-material culture to differentiate the contexts of social encounters, consumption, and exchange. Significantly, architecture (e.g., graded access), tableware (e.g., elaborate spouts), and faunal remains (e.g., structured deposition, anatomically selective treatment) also point to clearly compartmentalized EB and perhaps FN social life, with commensal and other social encounters divided into temporally and spatially distinct stages, perhaps with different groups of participants. Moreover, although evidence for such social engineering is much richer for the Bronze Age and perhaps FN, it is not entirely absent for earlier periods. Scarce EN ceramic tableware imitating wooden prototypes probably identified some commensal occasions as unusually important, while increasing diversity of MN and especially LN tableware and the emergence of ‘drinking sets’ suggest growing differentiation of commensal occasions, and probably participants, such that obligations of hospitality became increasingly context-specific and thus conditional. LN spatial or temporal segregation of initial carcass dressing from subsequent dismembering and filleting implies modest scope for the differential participation in successive stages of animal consumption that was greatly elaborated in the Bronze Age, while the highlighting of some commensal episodes at LN Toumba Kremastis-Koiladas, by structured deposition of dressed carcasses, presages a practice more widespread in FN and Bronze Age contexts. Finally, there are early hints of differential value of food and drink: LN jars lined with birch tar presumably held a beverage of some value; and the importance of animal symbolism in LN zoomorphic cups, LN display of bucrania on house fronts, and perhaps earlier Neolithic zoomorphic figurines (most probably representing cattle) offer emic support for earlier arguments regarding the high cultural importance of meat. Whether or not early cereal and pulse crops were valued differentially is more difficult to judge. It seems unlikely that consumers were indifferent to differences between crops in ease of growing and processing or to the contrast between toxic bitter vetch and non-toxic lentil, but such practically based variation in the attractiveness of different grains falls well short of the strong cultural connotations prevalent in the recent (and historical) past and also apparent in the LB texts. Archaeobotanical studies of storage contexts and animal dung are too sparse (and associated methodological problems too great) to determine systematically whether (and when) some grain crops were normally used as human food and others as animal fodder. Nonetheless, a cache of split and perhaps boiled seeds at EB Agios Athanasios and widespread finds of fully cleaned grain in storage contexts at later
Neolithic and EB Plata Magoula Zarkou\textsuperscript{110} and Mandalo\textsuperscript{111} and at LB Mycenae\textsuperscript{112} and Assiros Toumba\textsuperscript{113} suggest that bitter vetch, an unambiguous \textit{fodder crop} in the recent past, was regarded more favorably in later prehistory. On \textit{present evidence}, therefore, the sharp cultural distinctions between different staple grains, that are evident in the Linear B record, may tentatively be seen as a very ‘economical’ palatial innovation on the more ‘costly’ Neolithic strategy of differentiating commensal occasions and perhaps participants by provision of meat and rare beverages.

Bronze Age choreography of social life thus represents an intensification of Neolithic practices. Commensality seemingly played a significant role in \textit{negotiating} the transition from covert to overt social inequality, but may also have actively \textit{promoted} this change. The trend through the Neolithic to clearer household definition will have increased the potential to hoard surplus from good years rather than sharing it with neighbors, but the ‘shelf-life’ of grain is too short for storage alone to ensure the long-term livelihood of individual households. There will thus have been strong incentives to transform unused surplus: by feeding it to working cattle or adding indigent relatives and neighbors to the domestic workforce, and so securing additional labor for future production; or by hosting a feast that imposed an obligation on participants to reciprocate in kind, with labor or with other forms of support.\textsuperscript{114} In bad years, neighbors in need probably welcomed the opportunity to work for a diet of staple grains, but in good times a feast that imposed obligations is more likely to have been attractive if surplus grain had been converted to a higher-value form, such as beer or a fattened carcass. Hints from dental microwear, that livestock slaughtered for major commensal episodes at LN Makriyalos had been fattened on a soft diet, offer support for such conversion of staple grain to a more prestigious form. Attempts by individual households to enhance domestic food security and mobilize labor would thus have provided an important practical rationale for the increasingly competitive and conditional commensality that can be discerned in the later Neolithic of Greece and would arguably have contributed to the transformation of the overtly egalitarian societies of the Neolithic into the strikingly inegalitarian polities of the later Bronze Age. Underpinning this argument is the observation that, in recent rural Greece (see above), a hierarchy of food values was common to, and a source of linkage between, household strategies of diacritical commensality, labor mobilisation, investment of surplus, and risk buffering. This in turn highlights the need for an approach to commensal \textit{politics} that avoids a false opposition between ‘cultural’ and ‘practical’ reasoning,\textsuperscript{115} but rather situates the social stratagems and \textit{cultural} values of eating and drinking in company within the \textit{economic} practicalities of food production and commensal provisioning.
